

REMARKS

Claim 13 is under examination. With the this response, claim 13 has been amended and the term "osteoarthritis, rheumatoid arthritis" has been replaced with "pain associate with osteoarthritis or rheumatoid arthritis.". Support for this amendment can be found throughout the specification and, for example, at page 1, line 20 or page 8, line 8. The transition word in claim 13 has also been changed from "comprising" to "consisting essentially of" without prejudice. The claim has further been amended to replace the genus of iso-alpha acids with the specific species of that genus without prejudice. Support for this amendment can be found on page 8, line 9 of the application as filed. Reexamination and reconsideration in light of the foregoing amendments and following remarks is respectfully requested.

I. REJECTION UNDER 35 U.S.C. § 112, FIRST PARAGRAPH

Claim 13 stands rejected under 35 U.S.C. § 112, first paragraph as failing to comply with the enablement requirement. The Examiner states that "claim 13 is rejected . . . because the specification is not enabled for treating osteoarthritis, rheumatoid arthritis and acute pain (Office Action, page 3, lines 1-3). The Examiner states that "[t]he breadth of the claims is enormous" (Office Action, page 4, line 13) and that "[n]one of the diseases/conditions were tested in vivo and no positive conclusions were ever drawn" (Office Action, page 4, lines 21-22). On page 6 of the Office Action, the Examiner states that patients with osteoarthritis had to have been tested. The Examiner concludes by stating that "the claims do not find enablement from the instant specification" (Office Action, page 6, last line). Applicants respectfully disagree.

The enablement requirement is satisfied when one skilled in the art, after reading the specification, could practice the claimed invention without undue experimentation (AK Steel Corp. v. Sollac, 344 F.3d 1234, 1244 (Fed. Cir. 2003)). The court in *In re Wands* analyzed eight factors in determining undue experimentation. MPEP 2164.01(a)

specifically states that it "is improper to conclude a disclosure is not enabling based on an analysis of only one of the above factors while ignoring one or more of the others. The examiner's analysis must consider all the evidence related to each of these factors, and any conclusion of nonenableness must be based on the evidence as a whole."

However, the Examiner, in support of the instant enablement rejection, appears to have disproportionately based his arguments on only two of the *In re Wand's* factors, namely, the breadth of the claims and the existence of working examples. Although Applicants disagree with the reasoning offered by the Examiner, they have amended claim 13 solely to expedite the prosecution of the instant application and without acquiescing to any of the Examiner's reasons for this rejection. As amended, the breadth of the claim has been limited by replacing the term "osteoarthritis, rheumatoid arthritis" with "pain associate with osteoarthritis or rheumatoid arthritis," replacing the transition word "comprising" and replacing the genus of iso alpha acids with its species. Accordingly, Applicants submit that the breadth of the claim is no longer as broad as the Examiner described it to be.

Lack of *in-vivo* studies is the next issue that the Examiner has focused on in support of the enablement rejection and has mentioned at least four times on pages 4-6 of the Office Action. Applicants respectfully disagree with the Examiner and submit that although showing *in-vivo* data may be the requirement of a regulatory agency such as FDA, it is certainly not a requirement of the Patent Office or the enablement standard. As mentioned above, lack of working example is only one of the eight *In re Wand's* factors and cannot on its own be a determinative factor for whether or not the specification lacks enablement.

In deed, courts have recognized that "where, as here, the claimed invention is application of an unpredictable technology in the early stages of development, an enabling description in the specification must provide those skilled in the art with a specific and useful teaching, recognizing the stage of development of the technology." See *Genentech, Inc. v. Novo Nordisk A/S*, 108 F.3d 1361, 1367-68 (Fed. Cir. 1997).

The present application, rather than providing *in-vivo* data, has provided specific teachings as to the dosage parameters; referred to appropriate activity levels (i.e., the IC50-WHMA COX-2/COX-1 ratio) that is similar to that of other pain medications (e.g., NSAIDs that are commonly used in the treatment of acute pain or pain associated with osteoarthritis or rheumatoid); and cited a reference on how to determine these activity levels or adjust the dosage range (e.g., through the William Harvey Human Modified Whole Blood Assay (WHMA) as described in detail in cited reference T.D. Warner et al., Proc. Natl. Sci. USA 96:7563-68 (1999), incorporated by reference, on page 10, lines 10-13 of the specification, and a copy of which is included herewith). Indeed, WHMA is the type of study that has been routinely done for different compounds and the Examiner's assertion that a skilled artisan is not enabled to practice the invention as claimed is unfounded.

Therefore, and in view of the reasons provided above and those of record for other *In re Wands* factors, Applicants respectfully submit that the specification has provided sufficient disclosure for one skilled in the art to practice the claimed invention without undue experimentation. Applicants respectfully request the withdrawal of this rejection.

II. REJECTION UNDER 35 U.S.C. § 103(a)

Claims 13 stands rejected under 35 U.S.C. § 103(a) as being anticipated by Rigby et al (US 3,354,219; hereinafter "Rigby") in view of Todd, Jr et al (US 5,041,300) as evidenced by Medicinenet.com and About.com. In particular, the Examiner states that a bottle of beer produced in Todd contains an amount of isocalpha acids that falls within the range 5 mg to 1,000 mg claimed in claim 13. Office Action, page 8, third full paragraph. Applicants respectfully traverse the rejection for the reasons of record and the following reasons.

Applicants respectfully submit that claim 13 as amended is limited to administration of "pharmaceutical composition consisting essentially of a therapeutic quantity of a COX-2 inhibitor having a COX-2/COX-1 ratio of about 0.23 to about 3.33 . . . , wherein the

amount of the COX-2 inhibitor ranges from about 5 mg to about 1,000 mg per day." As such, Applicants respectfully submit that claim 13 as amended does not read on the Todd's beer composition because the claim is related to a composition 'consisting essentially' of a COX-2 inhibitor, and beer is not known to be a pharmaceutical COX-2 inhibitor let alone having a COX-2/COX-1 ratio of 0.23 to 3.33.

Therefore, Applicants respectfully submit that the ground for this rejection has been rendered moot as the references cited, alone or in combination, neither teach each and every element of the amended claim nor provide any motivation or expectation of success for one of skill in the art to combine the references to produce the instant invention. As such, based on the above reasons and the reasons of record, Applicants respectfully submit that Rigby in view of Todd, Jr et al (US 5,041,300) as evidenced by Medicinenet.com and About.com does not render amended claim 13 obvious and respectfully request withdrawal of the 35 U.S.C. § 103(a) rejection of claim 13.

III. DOUBLE PATENTING REJECTIONS

Claim 13 has been rejected on the ground of ground of nonstatutory double patenting over the claims of U.S. application No. 11409521, filed 4/21/2006, and U.S. patent No. 7279186, filed 01/09/2003. Applicants respectfully disagree on the basis that the above application and patent were both filed after the filing date of the instant application and are therefore not a proper subject for a nonstatutory double patenting rejection. As such, Applicants respectfully request withdrawal of these rejections.

IV. CONCLUSION

On the basis of the foregoing remarks and amendments, Applicants respectfully submit that amended Claims 13 is in condition for allowance. Passage to issue is respectfully requested.

If there are any questions regarding these remarks, the Examiner is encouraged to contact the undersigned at the telephone number provided below.

A Request for a Three (3) Month Extension of Time, up to and including May 24, 2010 (the next successive business day after the due date of May 23, 2010, which fell on a Sunday) is included herewith. Pursuant to 37 C.F.R. § 1.136(a)(3), the Examiner is authorized to charge any fee under 37 C.F.R. § 1.17 applicable in this instant, as well as in future communications, to Deposit Account 50-1133.

Furthermore, such authorization should be treated in any concurrent or future reply requiring a petition for an extension of time under paragraph 1.136 for its timely submission, as constructively incorporating a petition for extension of time for the appropriate length of time pursuant 37 C.F.R. § 1.136(a)(3) regardless of whether a separate petition is included.

Respectively submitted,

Nonsteroid drug selectivities for cyclo-oxygenase-1 rather than cyclo-oxygenase-2 are associated with human gastrointestinal toxicity: A full *in vitro* analysis

TIMOTHY D. WARNER^{1,†}, FRANCESCO GIULIANO², IVANA VOJNOVIC², JANE A. MITCHELL¹, AND JOHN R. VANE¹

¹The William Harvey Research Institute, St. Bartholomew's and the Royal London School of Medicine and Dentistry, Charterhouse Square, London, EC1M 6BQ, United Kingdom, and ²Department of Clinical Care Medicine, The Royal Brompton Hospital, Sydney Street, London SW3 6NP, United Kingdom

Contributed by John R. Vane, April 14, 1999

ABSTRACT The beneficial actions of nonsteroid anti-inflammatory drugs (NSAIDs) can be associated with inhibition of cyclo-oxygenase (COX)-2 whereas their harmful side effects appear to be associated with inhibition of cyclo-oxygenase-1 (COX-1). To test this hypothesis, we have compared the effects of NSAIDs on COX-1 and COX-2 from two related assay systems: the human whole blood assay and a modified human whole blood assay (using human A549 cells as a source of COX-2). This assay we refer to as the William Harvey Modified Assay. Our aim was to make meaningful comparisons of both classical NSAIDs and the newer COX-2 NSAIDs. Compounds that inhibit COX-1 and COX-2 in the blood assay and COX-1 in the modified assay, demonstrate a distribution of compound selectivities toward COX-1 that aligns with the risk of serious gastrointestinal complications. In conclusion, this full *in vitro* analysis of COX-1/2 selectivities in human tissues clearly supports the theory that inhibition of COX-1 underlies the gastrointestinal toxicity of NSAIDs in man.

Nonsteroid anti-inflammatory drugs (NSAIDs) are among the most widely prescribed drugs worldwide, being the drugs of first choice in the treatment of rheumatic disorders and other degenerative inflammatory joint diseases. Inhibition of cyclo-oxygenase (COX), and therefore prostaglandin production, is the common mechanism of action of the NSAIDs. (1). As is now well appreciated, COX exists in two isoforms, COX-1 and COX-2. COX-1 is constitutive and present in, for example, the endothelium, stomach and kidney whereas cyclo-oxygenase-2 (COX-2) is induced by proinflammatory cytokines and endotoxin *in cells in vitro* and at inflammatory sites *in vivo* (see ref. 2). This led some of us to the previous proposition that the side effects of NSAIDs are due to inhibition of COX-1 whereas the therapeutic, anti-inflammatory effects of these drugs are due to inhibition of COX-2 (3). A number of subsequent analyses have been published demonstrating the selectivities against COX-1 and COX-2 of a large number of NSAIDs and novel COX-2-selective inhibitors (see ref. 2). Although these analyses have used a wide range of assay systems, widely accepted is the human whole blood assay (4–7). This assay has the advantage of using readily available human cells and taking into account the binding of NSAIDs to human plasma proteins. However, thus far, there are no single studies published that compare the relative abilities of all members of the NSAID family to inhibit COX-1 and COX-2 in a common and appropriate assay system. Without such information, it is not possible to determine the predictive nature of such assays for the use of NSAIDs in the patient population. Here we present data derived from both the human whole blood assay (WBA) and a

human modified whole blood assay (WHMA) for ≥ 40 NSAIDs and COX-2 selective inhibitors. These data support the concept that inhibition of COX-1 is responsible for the serious gastrointestinal (GI) complications induced by NSAIDs in humans (8).

METHODS

Cell Culture. Human artery epithelial cells, A549 cells (European Collection of Animal Cell Cultures, ref. no. 86012804) were cultured in 96-well plates with DMEM supplemented with 10% fetal calf serum and 1- β -glutamine (4 mM). To induce the production of COX-2, A549 cells were exposed to interleukin-1 β (10 ng/ml⁻¹) for 24 h (9).

Human Whole Blood Assay (WBA). Blood was collected by venipuncture into heparin (19 units/ml) and then was aliquoted in 100- μ l volumes into the individual wells of 96-well plates. For COX-1 assays, blood then was treated with test agents or vehicle (usually 0.1% vol/vol dimethyl sulfoxide) followed 60 min later by aspirin (12 μ g/ml) and the plates were incubated for 6 h. For COX-2 assays, blood was removed and immediately frozen. For WBA COX-2 assays, blood was treated with aspirin (12 μ g/ml) to inactivate COX-1, and then 6 h later with lipopolysaccharide (10 μ g/ml) plus test agents or vehicle. Incubation then was continued for a further 18 h, after which time the plates were spun, and the plasma was removed and assayed for prostaglandin production as described (4). TXA₂ formation and so COX activity in samples from both protocols then were determined by radioimmunoassay. Data is reported as being from COX-1 and WBA-COX-2 protocols.

William Harvey Human Modified Whole Blood Assay (WHMA). For assay of COX-1, experiments were conducted as described for WBA. For assay of COX-2, the plasma from the plates was removed and immediately frozen. For WHMA COX-2 assays, blood was treated with aspirin (12 μ g/ml) to inactivate COX-1, and then 6 h later with lipopolysaccharide (10 μ g/ml) plus test agents or vehicle. Incubation then was continued for a further 18 h, after which time the plates were spun, and the plasma was removed (as above). The prostaglandin and TXA₂ in samples then were determined by radioimmunoassay as described (4). Data is reported as being from the A549 cells. Data is reported as being from the WHMA-COX-2 protocol.

Materials. Radiolabeled [3H]TXB₂ and [3H]PGE₂ were obtained from Amersham. Celecoxib, E-745,337, SC58125, and rofecoxib were synthesized by Hoechst Ingelheim; dimethyl sulfoxide was from Aldrich; aspirin was from BDH; interleukin-1 β (10 μ g/ml) added together with test agents or vehicle. Sixty minutes later, A23187 (50 μ M) was added, followed 30 min later by didodecyl (1 mM) to inhibit (>98%) the formation of prostanoins. The plates then were centrifuged, and plasma was removed (as above).

Frost Laboratories (Pointe Claire, PQ, Canada); tomoxipropic was a gift from NICOX S.A. (Nice, France); ketorolac, meclofenamate, and valeryl salicylate were obtained from Nufilmeac, NS308, and valeryl salicylate were obtained from SPI Bio (Massy Cedex, France); and salindac sulfide was purchased from Alfinni (Exeter, U.K.). All other compounds and reagents were obtained from Sigma.

Calculations. For each blood sample, the "control" formation of TXB₂ or PGE₂ was assessed as the mean of six determinations. For each experiment, the effects of the compounds were calculated and represented as percent of control by using the mean value of the concentration response curves were fitted, and the IC₅₀ and IC₂₅₀ values were determined as the ratios of COX-1/WBA:COX-2/WBA and COX-1/WBA:COX-2/WBA:IC₅₀ values, the IC₅₀ and IC₂₅₀ values.

RESULTS

Prostanoid Production. In the presence of drug vehicle, the productions of prostanoids in the assay systems were: COX-1, $32.3 \pm 1.9 \text{ ng mL}^{-1} \text{ TXB}_2$; WBA-COX-2, $12 \pm 0.6 \text{ ng mL}^{-1} \text{ TXB}_2$; and WHTMA-COX-2, $4.8 \pm 1.9 \text{ ng mL}^{-1} \text{ PGE}_2$ ($n = 24-31$). In blood treated with aspirin and then incubated for 18 h in the absence of lipopolysaccharide, there was no detectable formation of TXB₂ or PGE₂.

Inhibitor Potencies. The agonists tested previously divided into four groups in terms of their potencies as inhibitors of COX-1 and COX-2 (Table I; Figures 1–4).⁹ The first group consists of compounds that can produce full inhibition of both COX-1 and COX-2 at relatively poor selectivity. This group contained diclofenac, ibuprofen, naproxen, piroxicam, and sulfinate (Fig. 1) [the most potent inhibitor was diclofenac (IC_{50} 's = 6 nM)]. These could not be assessed in the WBA-COX-2 assay because of its instability in whole blood but were active in the WHMA-COX-2 assay.⁸ Taken together with the COX-1 assay, our data demonstrate that all three nonsteroidal anti-inflammatory drugs are second group compound containing compounds such as aspirin,⁷ acetaminophen,¹⁰ and rimexidine.¹¹

The third group contains compounds showing preferential selectivity toward COX-2 (>5-fold in the WHMA/COX-1 determination) (Fig. 1). It must not be overlooked, however, that these compounds also have the potential to produce full inhibition of COX-1. Interestingly, our data also indicate that celecoxib should be included here. Although it has been reported by others to inhibit primarily COX-2,¹² we found it inhibited COX-1 with only a very weak activity against COX-1 and included the experimental components diisopropyl fluorophosphate, 1,745,337, NS398, and SC58125 together with rofecoxib, all of which were designed as COX-2-selective agents (Fig. 2). The fourth group contained compounds that do not appear to interact directly with either COX-1 or -2, such as many of the salicylates. As expected, this fourth group also included nabumetone, which, unlike its metabolite EMNA, only produced weak inhibition of both COX isoforms.

DISCUSSION

Hence, using multiple assay systems, we have investigated the relative potencies as inhibitors of COX-1 and COX-2 of a wide range of NSAIDs as well as representatives of the newer COX-2 selective agents. In particular, however, we also included all of those agents which are known to act as agonists or antagonists of serotonergic receptors, since such compounds exerted (8). This was a deliberate choice, although some of these compounds were previously used in other human whole blood assays (e.g., refs. 4–7), they have not been tested together within a single assay system.

When comparing the potencies of NSAIDs against COX-1 and COX-2, IC₅₀ values are often used. However, there are assumptions underlying such an approach that are not necessarily correct, and it is therefore preferable to report the relative potencies, which are often not parallel. Thus, as the concentration of a NSAID increases, so does its relative potency. Second, NSAIDs are used therapeutically at doses that provide more than a 50% reduction

in prostaglandin formation. Indeed, a survey of the literature has established that, for diltiazem (10), diclofenac (11), indomethacin (12, 13), fenpropion (12), flurbiprofen (14), ketoprofen (12), ketorolac (13, 15), meclofenamate (15), meloxicam (16), naproxen (17), nimesulide (18), piroxicam (19), sulfadiazine (20), and tiarfenacin (21), the steady-state plasma concentrations of these drugs are in the range 10–1000 ng/ml. The *in vitro* IC₅₀ values for the production of prostaglandins by these NSAIDs are in the range 10–1000 nM (Table 1). Comparison of the potencies of the NSAIDs against COX-1 and COX-2 at the IC₅₀ value, therefore, appears to be more appropriate. In making these comparisons, we used data developed previously for the inhibition of COX-1 and COX-2 by prostaglandin formation are influenced by the supply of arachidonic acid both *in vitro* (21) and *in vivo* (22). Clearly, in the standardised human whole blood assay, there is a substantial difference between the time courses of the metabolites for testing inhibition of COX-1 and COX-2 (1 h vs. 18 h and, hence, in the rate of release of COX-2 metabolites from platelets). For prostaglandin metabolism in the human whole blood assay, A549 cells expressing COX-1 and COX-2 were used, in which COX-2-containing cells are exposed to NSAIDs for the same time periods and in which the same stimulus is applied at the end of this incubation period, as for the matched COX-1 assay system. Of interest, a number of the compounds tested appeared more potent in the WHEMA-COX-2 than the WBA-COX-2. This is consistent with the observation that the COX-2 active site has a higher binding affinity for compounds within the blood samples than the COX-1 active site. The different time courses of the WBA and WHEMA, therefore, it could be explained by different levels of sources of free arachidonic acid within the cells expressing COX-2 in the two assay systems, or even to the binding characteristics of the NSAIDs to COX-2 (23).

When the results of the comparisons from the two assay systems are considered, it is apparent that the agents tested could be divided into four main groups: (a) compounds capable of producing full inhibition of both COX-1 and COX-2 with poor selectivity; (b) compounds capable of producing full inhibition of COX-1 and COX-2 with preference for COX-2; (c) compounds that strongly inhibit COX-1 but only weakly or not at all against COX-1; and (d) compounds that inhibit both COX-1 and COX-2 with similar potencies and COX-2 (Table 1; Fig. 3). It is of interest to compare these findings to epidemiological studies of NSAID-induced GI toxicity. This is an area of particular interest, for NSAIDs cause serious gastric damage leading to hospitalisation in some 100,000 patients per year in the U.S. alone (24). The most likely mechanism for this is due to inhibition of GI compensations, thus, therefore, between NSAIDs use and the severity of GI complications. This has been reviewed recently (25). The results of the comparisons from most complete recent studies is a meta-analysis of reports between 1985 and 1994 (8) in which 11 NSAIDs (plus aspirin) were ordered for their association with serious complications. The order of the NSAIDs, from least to most damaging, was 1. ibuprofen, 2. diclofenac, 3. diflunisal, 4. fenpropion, 5. aspirin, 6. ketoprofen, and 11. tiarfenacin with aspirin, 7. ketorolac, 8. naproxen, 9. nimesulide, 10. piroxicam, 12. flurbiprofen, 13. fenpropion, 14. flurbiprofen, 15. meclofenamate, 16. meloxicam, 17. naproxen, 18. nimesulide, 19. piroxicam, 20. sulfadiazine, 21. tiarfenacin. Group 1 (see Table 1) contained all of the NSAIDs included in this analysis. This is consistent with the idea that NSAIDs produce serious GI complications by significantly inhibiting the activity of COX-1. Further comparison of the COX-1 inhibitory potencies of the NSAIDs with the *in vitro* IC₅₀ values for COX-1 associated with the greatest GI toxicity have the greatest COX-1 selectivity. These include tiarfenacin, indomethacin, ketoprofen (8), and, in particular, ketorolac. It is notable that we found ketorolac to be the most COX-1 selective of all of the NSAIDs we tested because this compound is ~5× more gastrotoxic than other NSAIDs (25). Clearly, this is in keeping with the idea that COX-1 inhibition is the primary mechanism for the GI toxicity of NSAIDs, and in particular, an extreme outlier both in our assay system and in epidemiological reports.

When making our comparisons from the two assay systems, we found that the agents tested could be divided into four main groups: (i) compounds capable of producing full inhibition of both COX-1 and COX-2 with poor selectivity; (ii) compounds capable of producing full inhibition of COX-1 and COX-2 with no evidence of producing full inhibition of COX-1 and COX-2 with only partial inhibition of COX-2; (iii) compounds that strongly inhibited COX-2 but not COX-1; and (iv) compounds that inhibited COX-1 but not COX-2. Year in the U.S. alone (24). The relationship between NSAIDs and the GI system is of the most complete, recent studies is a meta-analysis of reports between 1985 and 1994 (8) in which 11 NSAIDs (plus zidaprazolone) were ordered for their association with serious complications. The order of the NSAIDs, from least to most damaging, was: ibuprofen, 7; diclofenac, 8; flufenisal, 4; tieloprost, 5; aspirin, 6; rofenidone, 10; and 11-tolmetin, with zidaprazolone last. (We have not included zidaprazolone in any of our subsequent analyses). Group 1 (see Table 1) contained all of the NSAIDs included in this analysis. This is consistent with the idea that NSAIDs produce serious GI complications by significantly inhibiting the activity of COX-1. Further, comparison of the COX-1 selectivity associated with the greatest GI toxicity have the greatest COX-1 selectivity. These include tolmetin, indomethacin, ketoprofen (8), and, in particular, ketorolac. It is notable that we found ketorolac to be the most COX-1 selective of all of the NSAIDs we tested because this compound is $\sim 5\times$ more gastrotoxic than other NSAIDs (25). Interestingly, this is in keeping with the idea that COX-1 inhibition is an extreme outlier both in our assay system and in epidemiological reports.

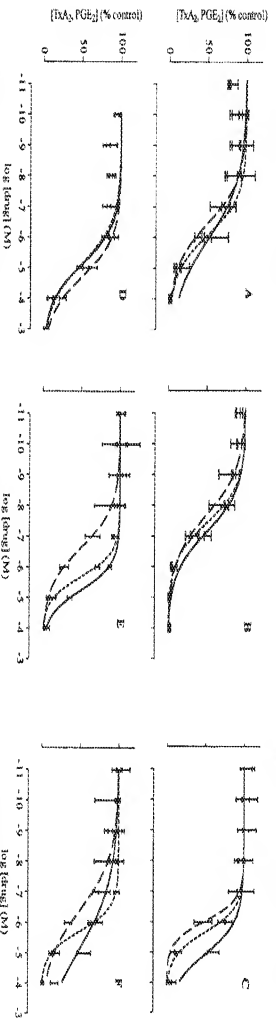

Fig. 1. The effects of celecoxib (*A*), diclofenac (*B*), etodolac (*C*), ibuprofen (*D*), meloxicam (*E*), and nimesulide (*F*) on the activity of COX-1 (solid line), COX-2 (short dashed line), and COX-1/2 (long dashed line). Results are expressed as percent of control and are pooled as mean \pm SEM. ($n = 5-8$).

can, however, has a much longer elimination half-life (30 to 70 h) (19) than other NSAIDs, and plasma half-life has been previously correlated with GI toxicity (27).

The second group of NSAIDs consists of preferential COX-2 inhibitors. In Fig. 3, we have classified these as compounds with between 5- and 50-fold selectivity for COX-2 over COX-1. This group includes celecoxib, which has been shown to inhibit COX-2 by 80% produce only 25% inhibition of COX-1. Despite the sparse epidemiological data, controlled trials [e.g., for an improved GI toxicity profile, it must be remembered, however, that increasing the dosage of these agents could readily increase GI toxicity (28, 29)] show that these preferential compounds have an improved GI toxicity profile. It must be remembered, however, that all of the compounds in this group are capable of inhibiting this isoform of COX (Fig. 1).

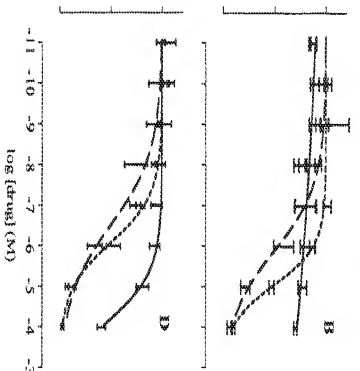

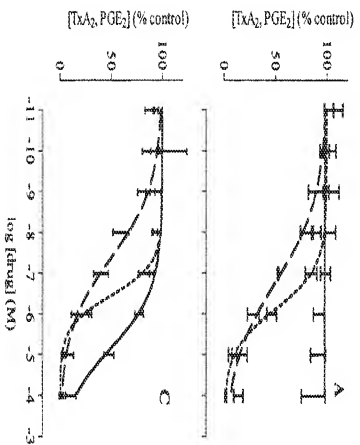

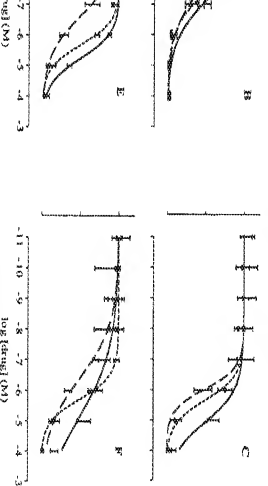

Fig. 2. The effects of disonoprost (*A*), L-745,337 (*B*), NS398 (*C*), and rofecoxib (*D*) on the activity of COX-1 (solid line), COX-2 (short dashed line), and COX-1/2 (long dashed line). Results are expressed as percent of control and are pooled as mean \pm SEM. ($n = 5-8$).

It is interesting that in our assays, celecoxib was found to be a member of the preferential group of COX-2 inhibitors. This is in contrast to data derived by using recombinant human COX-1 and COX-2 from insect cells. In this system, celecoxib is between 150- and 3,200-fold selective for COX-2 over COX-1 inhibition (19). It may be due to the fact that celecoxib inhibits both COX-1 and COX-2, but with a higher affinity for COX-1 than COX-2. There is a second, slow, time-dependent binding of celecoxib to COX-2 but not COX-1 that may well produce the selectively seen in other assay systems (25). It is selective in either the WBX or WHMA. It is unlikely that these assay systems in some way delay the time-dependent binding of celecoxib to COX-2. For instance, in the isolated human enzyme assays, this secondary binding takes place in seconds rather than hours, and the WBX assay included a 24-h incubation period.

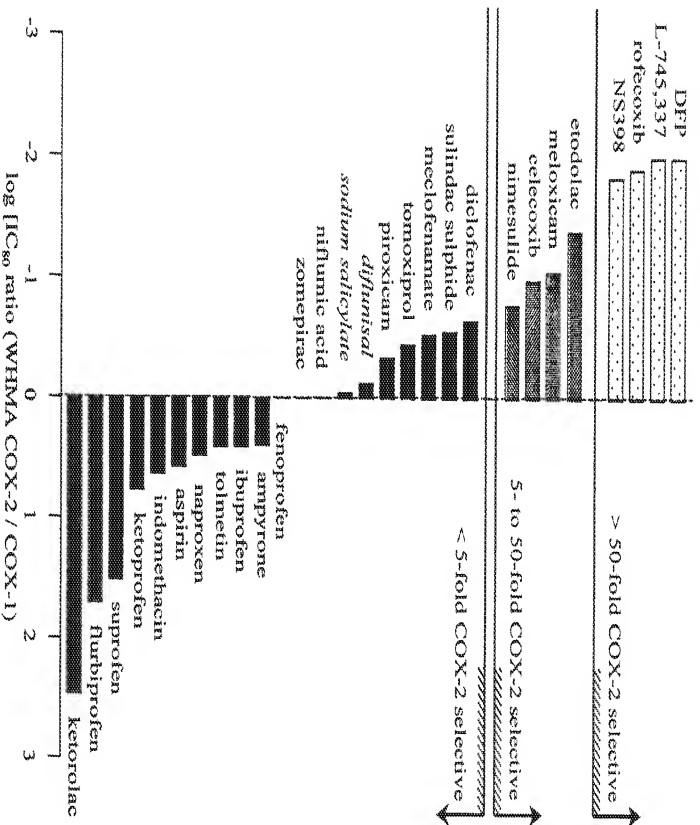

Fig. 3. Determinable log IC_{50} ratio (WBA:COX-2/COX-1) for all agents assayed (see Table 1). The group 1, with an IC_{50} ratio of 1, indicates compounds with very low potency.

Our data also reinforce the concept that compounds within group 3 that inhibit COX-2 with only a very weak activity against COX-1 will produce few serious GI complications when used in the general population. As is clear from both the direct inhibitor curves (Fig. 2) and the derived data (Figs. 3 and 4), these compounds have a high therapeutic window and should have a large therapeutic window. There are preliminary data that rofecoxib has a low GI toxicity, but, until appropriate comparative clinical trials have been completed, no firm conclusions can be drawn (30). Furthermore, it must be remembered that studies in animals (31) suggest that when used in the presence of existing GI damage, COX-2-selective inhibitors might slow the repair process in man due to reductions in the production of protective COX-1 (32).

Group 4 contains weak inhibitors of COX-1 and COX-2 for which reliable data with regard to inhibition of COX-1 and

COX-2 could not be derived. These compounds are not, therefore, displayed in Figs. 3 and 4. Clearly, however, the weak ability of the group 4 compounds to inhibit prostanoïd production explains their general lack of, or very low, GI toxicity. Sodium salicylate, for example, only caused inhibition of prostanoïd formation at concentrations far in excess of those achieved *in vivo* (13). The group 4 compounds have been previously classified as expected, this fourth group also contained nonsteroidal anti-inflammatories. This classification is in accordance with the results of Paragiani *et al.* (41) who found that oral dosing of nabumetone at 1 g per day for 7 days reduced COX-1 activity in the WBA by 70%. The plasma concentration of drug achieved with such dosing (34) would correlate with the activity of 60MNA but not nabumetone, which is a weak inhibitor of COX-1 (42). The classification of these agents, we would like to note that we also tested six additional
